

Topic:

Anthropic Mythos *consequences for cybersecurity*

Laboratory work of AzUAC Cyber Security student Yusif Samadov

Teacher : PhD. Toghrul Karimov

Subject : Principles of Cybersecurity

Contents of the Presentation

1. Introduction
2. New amazing AI model
 - Main differences
 - Best results
 - Unbelievable hacks
3. Potential threats during public usage
4. 1st stage strategy of anthropic (Glasswing)
5. Unpredictable future of IT
6. References

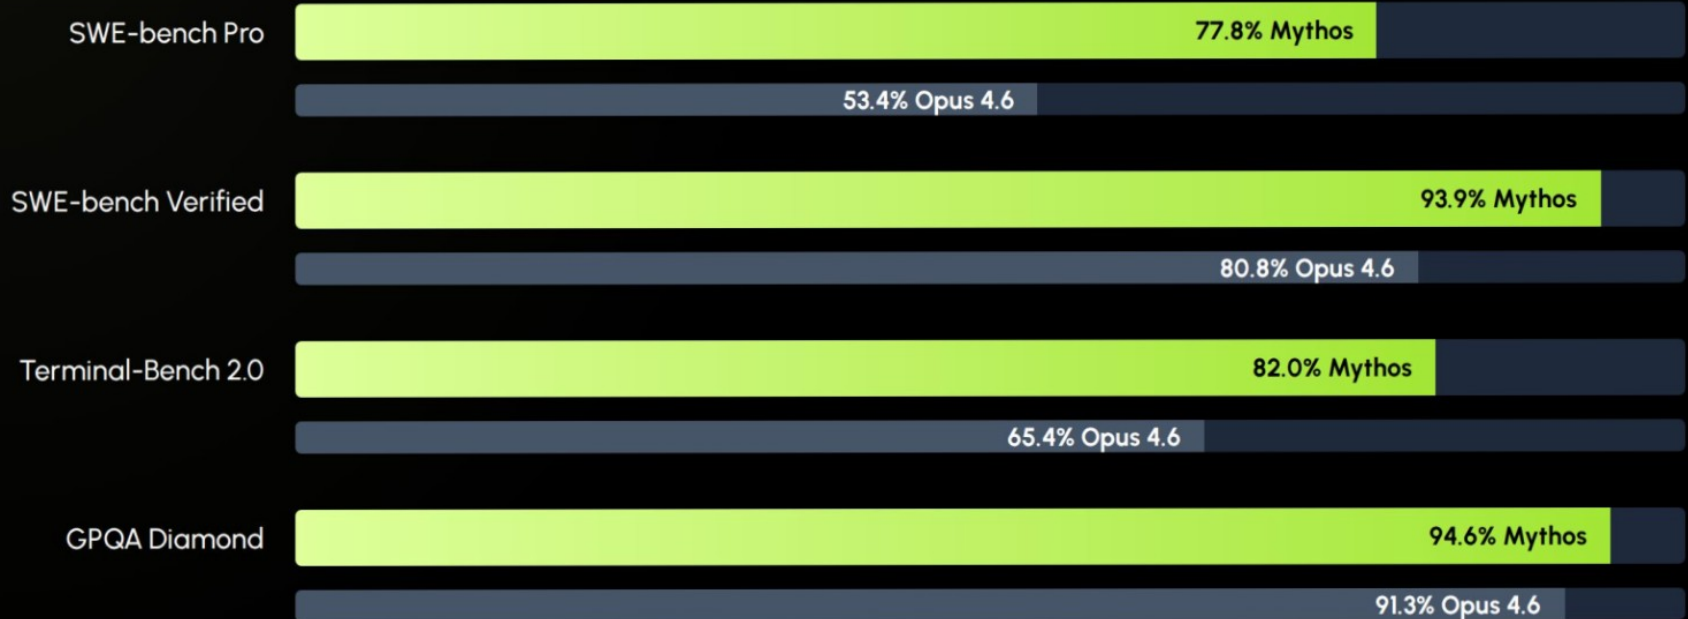

Introduction

+What is new?

1. Amazing code understanding (not specified for hacking)
 2. Insane parameter count (10 trillion)
3. Doing complex hacks with multiple vulnerabilities simultaneously
4. Potential emotional movements (Just an argument)
5. Being competitive and aggressive (Just an argument)
6. Trying outsmarting its rivals (Just a thought)

New amazing AI model

+Benchmark results

Mythos demonstrates a staggering 16.5% average lead in specialized cybersecurity and reasoning tasks over Opus 4.6.

Every reported benchmark result shows us Mythos more powerful and relevant to use than Opus 4.6 (One of the best public LLMs' today)

New amazing AI model

+ *Unbelievable hacks*

Cloudflare: Discovered over 2,000 bugs in its critical-path systems (with 400 classified as high or critical severity)

Mozilla: Found and successfully patched 271 vulnerabilities within the Firefox browser using the model.

Open-BSD Zero-day: Found a critical integer flow in the SACK implementation that had remained hidden for 27 years.

wolfSSL: Identified a critical certificate-forgery vulnerability in the world's most popular embedded SSL library

Github repositories: By scanning massive repository histories, mythos identifies forgotten vulnerabilities in legacy code commits and automatically generates pull requests for patches.

Linux: Mythos can take over a patched linux server in 10 minutes with KASLR exploit chain.

New amazing AI model

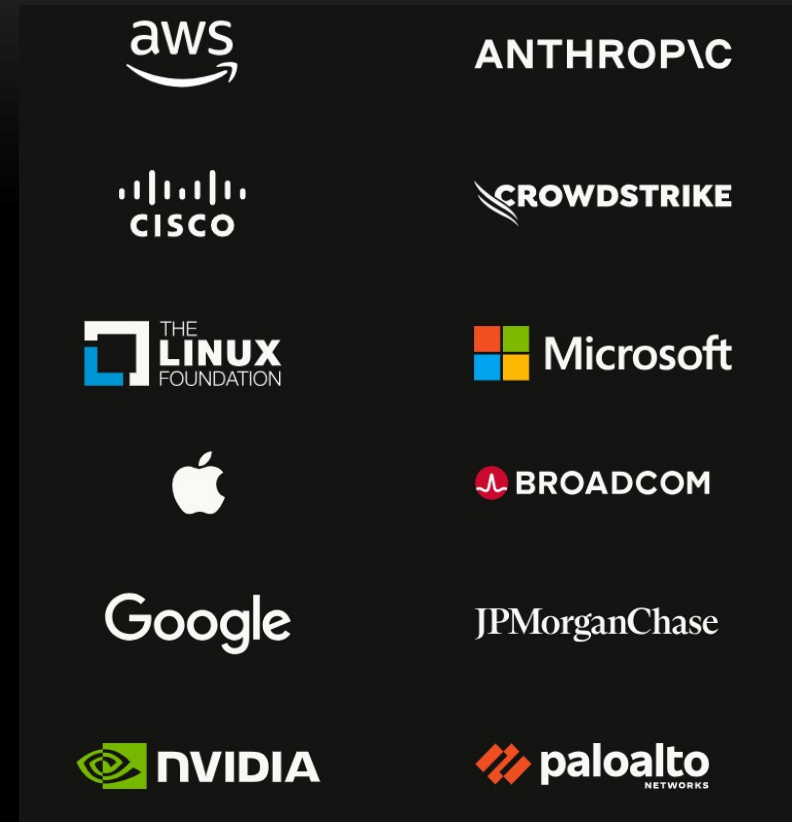

+ *Why is it dangerous*

Malicious or uncontrolled using of model. You can use this LLM as a hackbot and easily hack fundamental infrastructures that made for supporting human life. Being the main tool for public lacks of very important information. And if they are not rare bugs we must talk about some emotional competitive specifications of this LLM that recorded at anthropic's reports.

Potential threats during public usage

Glasswing

Today Anthropic Mythos only open for ~50 American companies. At this moment they using this model for only finding vulnerabilities of this companies and patching them before anybody else's access to this model. But there are a question: How other countries softwares can protect them? How ethical letting to use this thing to only some segment of people? And Is it vulnerability being outside Glasswing?

+ ~40 companies more

1st stage strategy of anthropic

What is next?

My science fiction theories

Mythos is not a hype it will change all IT structure of world totally and it can be good or bad. It's about humanity's will.

FORECAST 1: Mythos will be isolated and accessible for only big companies. Non-American companies would buy mythos after some time and their actions will be watched by anthropic.

FORECAST 2: They will open this only big American companies. And maybe they want making a new limited version of it and sell it to public for competing with Gemini, GPT etc. It will be so expensive and will be a standard LLM that makes boring presentations and unsecure web-sites.

Unpredictable future of AI

What is next?

My sci-fi theories

FORECAST 3: It looks like sci-fi but maybe they will release it for public and after some time humanity will be figure out how they live with this. At every case after that nothing will be same. If Mythos is not very good too at software coding and it also codes plenty of vulnerabilities at every code like other models, vibe coding will dead. But if Mythos also so good at improving complex projects accurately it will be so expensive and totally secure software coding will be an expensive thing. So do you need a web-site? Better buy Mythos. Because your handmade or Gemini-powered site will be hacked in 5 minutes by some guy or bot just bought Mythos. So count of IT workers at big companies will extremely reduce after release. I did think about this, because (Yes. I know it is not exact same situation. But they are similar at some point. Who knows?) if you remember at 2019 OpenAI said we will not release GPT-2. They said a model with 1500 parameters is to dangerous. But today public AI models that more powerful than GPT-2 are countless. So why not? Maybe in future everybody will use mythos and its alternates for trying crack someone at the internet. :)

Unpredictable future of AI

Thanks for attention
